

Package ‘catR’

June 15, 2010

Type Package

Title Procedures to generate IRT adaptive tests (CAT)

Version 1.1

Date 2010-06-15

Author David Magis (U Liege, Belgium), Gilles Raiche (UQAM, Canada)

Maintainer David Magis <david.magis@ulg.ac.be>

Depends R (>= 2.8.0)

Description The catR package allows the generation of response patterns under computerized adaptive testing (CAT) framework, with the choice of several starting rules, stopping rules and ability estimators.

License GPL (version 2 or later)

createItemBank	<i>Item bank generation</i>
----------------	-----------------------------

Description

This command creates an item bank from a matrix of item parameters. Item information functions are evaluated for all items and a fine grid of ability levels, to be supplied.

Usage

```
createItemBank(items=100, model="4PL", thMin=-4, thMax=4,
step=0.01, seed=1)
```

Arguments

<code>items</code>	either an integer value or a matrix of item parameters. See Details .
<code>model</code>	character: the name of the logistic IRT model, with possible values "1PL", "2PL", "3PL" or "4PL" (default). Ignored if <code>items</code> is a matrix.
<code>thMin</code>	numeric: the lower bound for the fine grid of ability levels (default is -4). See Details .
<code>thMax</code>	numeric: the upper bound for the fine grid of ability levels (default is 4). See Details .
<code>step</code>	numeric: the step value for the fine grid of ability levels (default is 0.01). See Details .
<code>seed</code>	numeric: the random seed number for the generation of item parameters (default is 1). See set.seed for further details.

Details

If `items` is a matrix, it has the following format: one row per item and four columns, with respectively the discrimination a_i , the difficulty b_i , the pseudo-guessing c_i and the inattention d_i parameters (Barton and Lord, 1981). If `items` is an integer, it corresponds to the number of items to be included in the item bank. Corresponding item parameters are (by default) randomly drawn from the following distributions: $a_i \sim N(1, 0.2^2)$, $b_i \sim N(0, 1)$, $c_i \sim U([0, 0.25])$ and $d_i \sim U([0.75, 1])$. Inattention parameters d_i are fixed to 1 if `model` is not "4PL"; pseudo-guessing parameters c_i are fixed to zero if `model` is either "1PL" or "2PL"; and discrimination parameters a_i are fixed to 1 if `model`="1PL". The random generation of item parameters can be controlled by the `seed` argument.

The item bank consists of a matrix of item information functions (Baker, 1992), evaluated for each item in the bank and at each value of a sequence of ability levels. These abilities are ranging from `thMin` to `thMax` by steps of `step` units.

The returned list contains in addition the sequence of ability levels and the matrix of item parameters.

Value

A list of class "itBank" with three arguments:

itemPar	the matrix of item parameters, either provided by <code>items</code> or generated.
theta	a vector with the ability levels of the fine grid, defined by arguments <code>thMin</code> , <code>thMax</code> and <code>step</code> .
infoTab	a matrix of item information functions, evaluated for each ability level (one row per ability level) and each item (one column per item).

eapEst

*EAP ability estimation under the 4PL model***Description**

This command returns the EAP (expected a posteriori) ability estimate for a given matrix of item parameters of the 4PL model and a given response pattern.

Usage

```
eapEst(it, x, D=1, priorDist="norm", priorPar=c(0,1),
       lower=-4, upper=4, nqp=20)
```

Arguments

<code>it</code>	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
<code>x</code>	numeric: a vector of dichotomous item responses.
<code>D</code>	numeric: the metric constant. Default is <code>D=1</code> (for logistic metric); <code>D=1.702</code> yields approximately the normal metric (Haley, 1952).
<code>priorDist</code>	character: specifies the prior distribution. Possible values are "norm" (default), "unif" and "Jeffreys".
<code>priorPar</code>	numeric: vector of two components specifying the prior parameters (default is <code>c(0,1)</code>). Ignored if <code>priorDist="Jeffreys"</code> . See Details .
<code>lower</code>	numeric: the lower bound for numerical integration (default is -4).
<code>upper</code>	numeric: the upper bound for numerical integration (default is 4).
<code>nqp</code>	numeric: the number of quadrature points (default is 20).

Details

The EAP (expected a posteriori) ability estimator (Bock and Mislevy, 1982) is obtained by computing the average of the posterior distribution of ability, set as the prior distribution times the likelihood function.

Three prior distributions are available: the normal distribution, the uniform distribution and Jeffreys' prior distribution (Jeffreys, 1939, 1946). The prior distribution is specified by the argument `priorDist`, with values "norm", "unif" and "Jeffreys", respectively.

The argument `priorPar` determines either the prior mean and standard deviation of the normal prior distribution (if `priorDist="norm"`), or the range for defining the prior uniform distribution (if `priorDist="unif"`). This argument is ignored if `priorDist="Jeffreys"`.

The required integrals are approximated by numerical adaptive quadrature using the [integrate](#) function. Arguments `lower`, `upper` and `nqp` define respectively the lower and upper bounds for numerical integration, and the number of quadrature points. By default, the numerical integration runs with 20 quadrature points on the range [-4; 4].

Value

The estimated EAP ability level.

eapSem

*Standard error of EAP ability estimation under the 4PL model***Description**

This command returns the estimated standard error of the ability estimate, for a given matrix of item parameters of the 4PL model, an ability estimate and a specified estimator.

Usage

```
eapSem(thEst, it, x, D=1, priorDist="norm", priorPar=c(0,1),
       lower=-4, upper=4, nqp=20)
```

Arguments

thEst	numeric: the EAP ability estimate.
it	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
x	numeric: a vector of dichotomous item responses.
D	numeric: the metric constant. Default is $D=1$ (for logistic metric); $D=1.702$ yields approximately the normal metric (Haley, 1952).
priorDist	character: specifies the prior distribution. Possible values are "norm" (default), "unif" and "Jeffreys".
priorPar	numeric: vector of two components specifying the prior parameters (default is $c(0,1)$). Ignored if <code>priorDist="Jeffreys"</code> . See Details .
lower	numeric: the lower bound for numerical integration (default is -4).
upper	numeric: the upper bound for numerical integration (default is 4).
nqp	numeric: the number of quadrature points (default is 20).

Details

This command computes the standard error of the EAP (expected a posteriori) ability estimator (Bock and Mislevy, 1982).

Three prior distributions are available: the normal distribution, the uniform distribution and Jeffreys' prior distribution (Jeffreys, 1939, 1946). The prior distribution is specified by the argument `priorDist`, with values "norm", "unif" and "Jeffreys", respectively.

The argument `priorPar` determines either the prior mean and standard deviation of the normal prior distribution (if `priorDist="norm"`), or the range for defining the prior uniform distribution (if `priorDist="unif"`). This argument is ignored if `priorDist="Jeffreys"`.

The required integrals are approximated by numerical adaptive quadrature using the `integrate` function. Arguments `lower`, `upper` and `nqp` define respectively the lower and upper bounds for numerical integration, and the number of quadrature points. By default, the numerical integration runs with 20 quadrature points on the range $[-4; 4]$.

Note that in the current version, the EAP ability estimate must be specified through the `thEst` argument.

Value

The estimated standard error of the EAP ability level.

Ii

*Item information functions, first and second derivatives (4PL)***Description**

This command returns the item information functions for a given matrix of item parameters of the 4PL model and a given ability value. Numerical values of the first and second derivatives of the item information functions are also returned.

Usage

```
Ii(th, it, D=1)
```

Arguments

th	numeric: the ability value.
it	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
D	numeric: the metric constant. Default is D=1 (for logistic metric); D=1.702 yields approximately the normal metric (Haley, 1952).

Details

The first and second derivatives are computed algebraically from the four-parameter logistic (4PL) model (Barton and Lord, 1981). These derivatives are necessary for both the estimation of ability and the computation of related standard errors.

Value

A list with three arguments:

Ii	the vector with item informations (one value per item)
dIi	the vector with first derivatives of the item information functions (one value per item)
d2Ii	the vector with second derivatives of the item information functions (one value per item)

nextItem

Selection of the next item

Description

This command selects the next item to be administered, given the list of previously administered items and the current ability estimate, with the 'maximum information' criterion.

Usage

```
nextItem(itemBank, theta, out=NULL, method="info")
```

Arguments

itemBank	an item bank of class <code>itBank</code> as output of the function createItemBank .
theta	numeric: the current value of the ability estimate.
out	either a vector of integer values specifying the items previously administered, or NULL (default).
method	character: the method for next item selection, either "info" (default) or "Owen". See Details .

Details

Currently two methods are available for selecting the next item to be administered in the adaptive test. For a given current ability estimate, the next item is selected (among the available items) either using the information criterion or using Owen's procedure (Owen, 1975). The information criterion selects the next item as the one which maximizes the item information function (Baker, 1992). The most informative item is selected from the table of item informations provided by the bank of items specified with `itemBank`. Owen's procedure consists in selecting as next the item whose difficulty level is closest to the current ability estimate. Under the IPL model, both methods are equivalent.

The method for next item selection is specified by the `method` argument. Possible values are "info" for the information criterion, and "Owen" for Owen's method. Other values return an error message.

The available items are those that are not specified in the `out` argument. By default, `out` is `NULL`, which means that all items are available.

Value

A list with three arguments:

<code>item</code>	the selected item (identified by its number in the item bank).
<code>par</code>	the vector of item parameters of the selected item.
<code>info</code>	the value of the information function for the selected item and the current ability estimate.
<code>method</code>	the value of the <code>method</code> argument.

Pi

*Item response probabilities, first, second and third derivatives (4PL)***Description**

This command returns the item response probabilities for a given matrix of item parameters of the 4PL model and a given ability value. Numerical values of the first, second and third derivatives of the response probabilities are also returned.

Usage

```
Pi(th, it, D=1)
```

Arguments

th	numeric: the ability value.
it	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
D	numeric: the metric constant. Default is D=1 (for logistic metric); D=1.702 yields approximately the normal metric (Haley, 1952).

Details

The first, second and third derivatives are computed algebraically from the four-parameter logistic (4PL) model (Barton and Lord, 1981). These derivatives are necessary for both the estimation of ability and the computation of related standard errors.

Value

A list with four arguments:

<i>Pi</i>	the vector with response probabilities (one value per item)
<i>dPi</i>	the vector with first derivatives of the response probabilities (one value per item)
<i>d2Pi</i>	the vector with second derivatives of the response probabilities (one value per item)
<i>d3Pi</i>	the vector with third derivatives of the response probabilities (one value per item)

randomCAT

*Random generation of adaptive tests***Description**

This command generates a response pattern to an adaptive test, for a given item bank, a true ability level, and several lists of CAT parameters (starting items, stopping rule, provisional and final ability estimators).

Usage

```
randomCAT(trueTheta, itemBank, maxItems=50,
  start=list(fixItems=NULL, seed=NULL, nrItems=1, theta=0,
    bw=4, range=c(-4,4)), test=list(method="BM",
    priorDist="norm", priorPar=c(0,1), range=c(-4,4), D=1,
    eapPar=c(-4,4,20), itemSelect="info"),
  stop=list(rule="length", thr=20, alpha=0.05),
  final=list(method="BM", priorDist="norm",
    priorPar=c(0,1), range=c(-4,4), D=1, eapPar=c(-4,4,20),
    alpha=0.05))
  ## S3 method for class 'cat':
print(x, ...)
  ## S3 method for class 'cat':
plot(x, ci=TRUE, alpha=0.05, thr=NULL, ...)
```

Arguments

<code>trueTheta</code>	numeric: the value of the true ability level.
<code>itemBank</code>	an item bank, i.e. a list of class <code>itBank</code> , typically an output of the function <code>createItemBank</code> .
<code>maxItems</code>	numeric: the maximal number of items to be administered (default is 50).
<code>start</code>	a list with the options for starting the adaptive test. See Details .
<code>test</code>	a list with the options for provisional ability estimation and next item selection. See Details .
<code>stop</code>	a list with the options of the stopping rule. See Details .
<code>final</code>	a list with the options for final ability estimation. See Details .
<code>x</code>	an object of class "cat", typically an output of <code>randomCAT</code> function.
<code>ci</code>	logical: should the confidence intervals be plotted for each provisional ability estimate? (default is TRUE).
<code>alpha</code>	numeric: the significance level for provisional confidence intervals (default is 0.05). Ignored if <code>ci</code> is FALSE.
<code>thr</code>	either a numeric value specifying the threshold to be plotted, or NULL (default) for not displaying any threshold.
<code>...</code>	other generic arguments to be passed to <code>print</code> and <code>plot</code> functions.

Details

The `randomCAT` function generates an adaptive test using an item bank specified by argument `itemBank`, and for a given true ability level specified by argument `trueTheta`. The maximal length of the test can be fixed through the `maxItems` argument, with a default value of 50 items.

The test specification is made by means of four lists of options: one list for the selection of the starting items, one list with the options for provisional ability estimation, one list to define the stopping rule, and one list with the options for final ability estimation. These lists are specified respectively by the arguments `start`, `test`, `stop` and `final`.

The `start` list can contain one or several of the following arguments:

- `fixItems`: either a vector of integer values, setting the items to be administered as first items, or `NULL` (default) to let the function select the items.
- `seed`: either a numeric value to fix the random seed for item selection, or `NULL` (default) to select the items on the basis of their difficulty level. Ignored if `fixItems` is not `NULL`.
- `nrItems`: the number of first items to be selected (default is 1). Ignored if `fixItems` is not `NULL`.
- `theta`: the central initial ability value, used to define the range of ability levels for selecting the first items (default is 0). Ignored if either `fixItems` or `seed` is not `NULL`. See [startItems](#) for further details.
- `bw`: the bandwidth value, used to define the range of ability levels for selecting the first items (default is 4). Ignored if either `fixItems` or `seed` is not `NULL`. See [startItems](#) for further details.
- `range`: the maximal range of difficulty levels, specified as a vector of two numeric values (default is `c(-4, 4)`). Ignored if either `fixItems` or `seed` is not `NULL`. See [startItems](#) for further details.

These arguments are passed to the function [startItems](#) to select the first items of the test.

The `test` list can contain one or several of the following arguments:

- `method`: a character string to specify the method for ability estimation. Possible values are: "BM" (default) for Bayesian modal estimation (Birnbaum, 1969), "ML" for maximum likelihood estimation (Lord, 1980), "EAP" for expected a posteriori (EAP) estimation (Bock and Mislevy, 1982), and "WL" for weighted likelihood estimation (Warm, 1989).
- `priorDist`: a character string which sets the prior distribution. Possible values are: "norm" (default) for normal distribution, "unif" for uniform distribution, and "Jeffreys" for Jeffreys' noninformative prior distribution (Jeffreys, 1939, 1946). ignored if `method` is neither "BM" nor "EAP".
- `priorPar`: a vector of two numeric components, which sets the parameters of the prior distribution. If (`method="BM"` or `method=="EAP"`) and `priorDist="norm"`, the components of `priorPar` are respectively the mean and the standard deviation of the prior normal density. If (`method="BM"` or `method=="EAP"`) and `priorDist="unif"`, the components of `priorPar` are respectively the lower and upper bound of the prior uniform density. Ignored in all other cases. By default, `priorPar` takes the parameters of the prior standard normal distribution (i.e., `priorPar=c(0, 1)`).
- `range`: the maximal range of ability levels, set as a vector of two numeric components. The ability estimate will always lie to this interval (set by default to `[-4, 4]`). Ignored if `method=="EAP"`.
- `D`: the value of the metric constant. Default is `D=1` for logistic metric. Setting `D=1.702` yields approximately the normal metric (Haley, 1952).

- `eapPnumeric`: vector of three components, holding respectively the values of the arguments `lower`, `upper` and `nqp` of the `eapEst` command. Default vector is (-4, 4, 20). Ignored if method is not "EAP".
- `itemSelectcharacter`: the rule for next item selection, with values "info" (default) for maximum information criterion or "Owen" for Owen's procedure. See `nextItem` for further details.

These arguments are passed to the functions `thetaEst` (or `eapEst`) and `semTheta` (or `eapSem`) to estimate the ability level and the standard error of this estimate.

The `stop` list can contain one or several of the following arguments:

- `rule`: a character string specifying the type of stopping rule. Possible values are: "length" (default), to stop the test after a pre-specified number of items administered; "precision", to stop the test when the provisional standard error of ability becomes less than or equal to the pre-specified value; and "classification", for which the test ends whenever the provisional confidence interval (set by the `alpha` argument) does not hold the classification threshold anymore.
- `thr`: a numeric value fixing the threshold of the stopping rule. If `rule="length"`, `thr` is the maximal number of items to be administered (in practice, it is replaced by the value of the `maxItems` argument if the latter is smaller than `thr`). If `rule="precision"`, `thr` is the precision level (i.e. the standard error) to be reached before stopping. Finally, if `rule="classification"`, `thr` corresponds to the ability level which serves as a classification rule (i.e. which must not be covered by the provisional confidence interval).
- `alpha`: the significance (or α) level for computing the provisional confidence interval of ability. Ignored if `rule` is not "classification".

Eventually, the `final` list can contain one or several arguments of the `test` list (with possibly different values), as well as the additional `alpha` argument. The latter specifies the α level of the final confidence interval of ability, which is computed as

$$[\hat{\theta} - z_{1-\alpha/2} se(\hat{\theta}); \hat{\theta} + z_{1-\alpha/2} se(\hat{\theta})]$$

where $\hat{\theta}$ and $se(\hat{\theta})$ are respectively the ability estimate and its standard error. Note that the argument `itemSelect` of the `test` list is not allowed into the `final` list.

If some arguments of these lists are missing, they are automatically set to their default value. The contents of the lists is checked with the `testList` function, and the adaptive test is generated only if the lists are adequately defined. Otherwise, a message error is printed.

The function `plot.cat` represents the set of provisional and final ability estimates throughout the test. Corresponding confidence intervals (with confidence level defined by the argument `alpha`) are also drawn if `ci=TRUE` (which is the default value). In addition, a classification threshold can be displayed by specifying a numeric value to the argument `thr`. The default value `NULL` does not represent any threshold.

Value

The function `randomCAT` returns a list of class "cat" with the following arguments:

<code>trueTheta</code>	the value of the <code>trueTheta</code> argument.
<code>maxItems</code>	the value of the <code>maxItems</code> argument.
<code>testItems</code>	a vector with the items that were administered during the test.
<code>itemPar</code>	a matrix with the parameters of the items administered during the test.

<code>pattern</code>	the generated response pattern (as vector of 0 and 1 entries).
<code>thetaProv</code>	a vector with the provisional ability estimates.
<code>seprov</code>	a vector with the standard errors of the provisional ability estimates.
<code>thFinal</code>	the final ability estimate.
<code>seFinal</code>	the standrad error of the final ability estimate.
<code>ciFinal</code>	the confidence interval of the final ability estimate.
<code>startFixItems</code>	the value of the <code>start\$fixItems</code> argument (or its default value if missing).
<code>startSeed</code>	the value of the <code>start\$seed</code> argument (or its default value if missing).
<code>startNrItems</code>	the value of the <code>start\$nrItems</code> argument (or its default value if missing).
<code>startTheta</code>	the value of the <code>start\$theta</code> argument (or its default value if missing).
<code>startBw</code>	the value of the <code>start\$bw</code> argument (or its default value if missing).
<code>startbOpt</code>	the value of the <code>start\$bOpt</code> argument (or its default value if missing).
<code>startRange</code>	the value of the <code>start\$range</code> argument (or its default value if missing).
<code>provMethod</code>	the value of the <code>test\$method</code> argument (or its default value if missing).
<code>provDist</code>	the value of the <code>test\$priorDist</code> argument (or its default value if missing).
<code>provPar</code>	the value of the <code>test\$priorPar</code> argument (or its default value if missing).
<code>provRange</code>	the value of the <code>test\$range</code> argument (or its default value if missing).
<code>provD</code>	the value of the <code>test\$D</code> argument (or its default value if missing).
<code>itemSelect</code>	the value of the <code>test\$itemSelect</code> argument (or its default value if missing).
<code>stopRule</code>	the value of the <code>stop\$rule</code> argument (or its default value if missing).
<code>stopThr</code>	the value of the <code>stop\$thr</code> argument (or its default value if missing).
<code>stopAlpha</code>	the value of the <code>stop\$alpha</code> argument (or its default value if missing).
<code>endWarning</code>	a logical indactor indicating whether the adaptive test stopped because the stopping rule was satisfied or not.
<code>finalMethod</code>	the value of the <code>final\$method</code> argument (or its default value if missing).
<code>finalDist</code>	the value of the <code>final\$priorDist</code> argument (or its default value if missing).
<code>finalPar</code>	the value of the <code>final\$priorPar</code> argument (or its default value if missing).
<code>finalRange</code>	the value of the <code>final\$range</code> argument (or its default value if missing).
<code>finalD</code>	the value of the <code>final\$D</code> argument (or its default value if missing).
<code>finalAlpha</code>	the value of the <code>final\$alpha</code> argument (or its default value if missing).

The function `print.cat` returns similar (but differently organized) results.

semTheta

Standard error of ability estimation under the 4PL model

Description

This command returns the estimated standard error of the ability estimate, for a given matrix of item parameters of the 4PL model, an ability estimate and a specified estimator.

Usage

```
semTheta(thEst, it, x=NULL, D=1, method="BM", priorDist="norm",
  priorPar=c(0,1), eapPar=c(-4,4,20))
```

Arguments

thEst	numeric: the ability estimate.
it	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
x	numeric: a vector of dichotomous item responses (default is NULL). Ignored if method is not "EAP".

D	numeric: the metric constant. Default is $D=1$ (for logistic metric); $D=1.702$ yields approximately the normal metric (Haley, 1952).
method	character: the ability estimator. Possible values are "BM" (default), "ML" and "WL". See Details .
priorDist	character: specifies the prior distribution. Possible values are "norm" (default), "unif" and "Jeffreys". Ignored if method is neither "BM" nor "EAP". See Details .
priorPar	numeric: vector of two components specifying the prior parameters (default is $c(0, 1)$). Ignored if method is neither "BM" nor "EAP", or if priorDist="Jeffreys". See Details .
eapPar	numeric: vector of three components, holding respectively the values of the arguments lower, upper and nqp of the <code>eapEst</code> command. Default vector is $(-4, 4, 20)$. Ignored if method is not "EAP".

Details

Four ability estimators are available: the maximum likelihood (ML) estimator (Lord, 1980), the Bayes modal (BM) estimator (Birnbaum, 1969), the expected a posteriori (EAP) estimator (Bock and Mislevy, 1982) and the weighted likelihood (WL) estimator (Warm, 1989). The selected estimator is specified by the `method` argument, with values "ML", "BM", "EAP" and "WL" respectively.

For the BM and EAP estimators, three prior distributions are available: the normal distribution, the uniform distribution and the Jeffreys' prior distribution (Jeffreys, 1939, 1946). The prior distribution is specified by the argument `priorPar`, with values "norm", "unif" and "Jeffreys", respectively. The `priorPar` argument is ignored if `method="ML"` or `method="WL"`.

The argument `priorPar` determines either: the prior mean and standard deviation of the normal prior distribution (if `priorDist="norm"`), or the range for defining the prior uniform distribution (if `priorDist="unif"`). This argument is ignored if `priorDist="Jeffreys"`.

The `eapPar` argument sets the range and the number of quadrature points for numerical integration in the EAP process. By default, it takes the vector value $(-4, 4, 20)$, that is, 20 quadrature points on the range $[-4; 4]$. See `eapEst` for further details.

Note that in the current version, the ability estimate must be specified through the `thEst` argument. Moreover, the response pattern must be specified through the `x` argument to compute the standard error of the EAP estimate. For the other estimation methods, this is not necessary, and `x` is set to `NULL` by default for this purpose.

Value

The estimated standard error of the ability level.

## End(Not run)
```

startItems	<i>Selection of the first items</i>
------------	-------------------------------------

Description

This command selects the first items of the adaptive test, either randomly or on the basis of their difficulty level.

Usage

```
startItems(it, fixItems=NULL, seed=NULL, nrItems=1,
            theta=0, bw=4, range=c(-4,4))
```

Arguments

<code>it</code>	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
<code>fixItems</code>	either a vector of integer values or <code>NULL</code> (default). See Details .
<code>seed</code>	either a numeric value or <code>NULL</code> (default). See Details .
<code>nrItems</code>	numeric: the number of starting items to be selected (default is 1). Ignored if <code>fixItems</code> is not <code>NULL</code> .
<code>theta</code>	numeric: the initial ability level for selecting the first items (default is 0). Ignored if either <code>fixItems</code> or <code>seed</code> is not <code>NULL</code> . See Details .
<code>bw</code>	numeric: the length (bandwidth) of the difficulty interval for selecting the first items (default is 4). Ignored if either <code>fixItems</code> or <code>seed</code> is not <code>NULL</code> . See Details .
<code>range</code>	numeric: the range of difficulty levels for selecting the first items (default is <code>c(-4,4)</code>). Ignored if either <code>fixItems</code> or <code>seed</code> is not <code>NULL</code> . See Details .

Details

The first items of the adaptive test can be selected either by fixing these items or by some selection into the item bank. The first items can be fixed by specifying `fixItems` as a vector of integer values, each value referring to the corresponding item in the item bank.

If `fixItems` is kept to `NULL` (the default choice), then `nrItems` will be selected, either randomly or according to their difficulty level. In the former, one has to assign a numeric value to the `seed` argument. In the latter, `seed` is kept to `NULL` (the default value) and the items are selected as follows. The arguments `theta` and `bw` permit to define a sequence of value, ranging from `theta - bw` to `theta + bw` and of length `nrItems` (if `nrItems` equals 1, the range reduces to `theta`). Then, for each value in the sequence, the function selects the item in the item bank with difficulty level as close as possible to the sequential value. By default, `theta` equals 0 and `bw` equals 4, meaning that the sequence ranges from -4 to 4 and of length `nrItems`.

The argument `range` permits to constraint the range of difficulty levels, by default to the range [-4, 4].

Value

A list with three arguments:

<code>items</code>	the selected items (identified by their number in the item bank).
<code>par</code>	the matrix of item parameters of the selected items (one row per item).
<code>bOpt</code>	the values of the item difficulties chosen for selecting the first items.

tcals

Items parameters of the TCALS 1998 data set

Description

The TCALS (*Test d'Aptitude en Anglais Langue Seconde*) is an aptitude test of English language as a second language in the French speaking college of Outaouais (Gatineau, QC, Canada). The test consists of 85 items and is administered every year to newly incoming students. The item parameters of the year 1998 have been estimated under the 3PL model. Inattention parameters are therefore fixed to one.

Format

A matrix with 85 rows and four columns, respectively holding the discrimination, difficulty, pseudo-guessing and inattention parameters as calibrated on the results of the 1998 application of the TCALS questionnaire.

Source

The TCALS test was originally developed by Laurier, Froio, Pearo and Fournier (1998) and item parameters were obtained from Raiche (2002)..

References

Laurier, M., Froio, L., Pearo C., and Fournier, M. (1998). Test de classement d'anglais langue seconde au collegial. Montreal, Canada: College de Maisonneuve.

testList

Testing the format of the input lists

Description

This command tests whether format of the input lists for the random generation of adaptive tests is convenient, and returns a warning message otherwise.

Usage

```
testList(list, type="start")
```

Arguments

<code>list</code>	a list of arguments to be tested. See Details .
<code>type</code>	character: the type of list for checking. Possible values are "start" (default), "test", "stop" and "final". See Details .

Details

The `testList` function checks whether the list provided in the `list` argument is accurate for the selected `type`. It mainly serves as an initial check for the `randomCAT` function.

The four types of lists are: "start" with the parameters for selecting the first items; "test" with the options of the adaptive test (i.e. method for next item selection, provisional ability estimator and related information); "stop" with the options setting the stopping rule; and "final" with the options for final ability estimation. See the help file of `randomCAT` for further details about the different lists, their allowed arguments and their contents.

The function returns an "ok" message if the arguments of `list` match the requirement of the corresponding `type`. Otherwise, a message is returned with information about list - type mismatch. This will be the case if:

- `list` is not a list, or has no argument names,
- `list` has too many arguments for the `type` specified,
- one of the argument names is incorrect,
- the contents of an argument is not adequate (e.g. character instead of numeric).

Each mismatch yields a different output message to help in debugging the problem.

Value

A list with two arguments:

<code>test</code>	a logical value indicating whether the format of the list is accurate (TRUE) or not (FALSE).
<code>message</code>	either a message to indicate the type of misspecification, or "ok" if the format is accurate.

thetaEst

Ability estimation under the 4PL model

Description

This command returns the ability estimate for a given matrix of item parameters of the 4PL model and a given response pattern. Available estimators are maximum likelihood, Bayes modal, expected a posteriori (EAP) and weighted likelihood.

Usage

```

thetaEst(it, x, D=1, method="BM", priorDist="norm",
  priorPar=c(0,1), range=c(-4,4),
  eapPar=c(-4,4,20))

```

Arguments

it	numeric: a matrix with one row per item and four columns, with the values of the discrimination, the difficulty, the pseudo-guessing and the inattention parameters (in this order).
x	numeric: a vector of dichotomous item responses.
D	numeric: the metric constant. Default is D=1 (for logistic metric); D=1.702 yields approximately the normal metric (Haley, 1952).
method	character: the ability estimator. Possible values are "BM" (default), "ML" and "WL". See Details .
priorDist	character: specifies the prior distribution. Possible values are "norm" (default), "unif" and "Jeffreys". Ignored if method is neither "BM" nor "EAP". See Details .
priorPar	numeric: vector of two components specifying the prior parameters (default is c(0,1)). Ignored if method is neither "BM" nor "EAP", or if priorDist="Jeffreys". See Details .

range	numeric: vector of two components specifying the range wherein the ability estimate must be looked for (default is $c(-4, 4)$). Ignored if <code>method=="EAP"</code> .
eapPar	numeric: vector of three components, holding respectively the values of the arguments <code>lower</code> , <code>upper</code> and <code>nqp</code> of the <code>eapEst</code> command. Default vector is $(-4, 4, 20)$. Ignored if <code>method</code> is not "EAP".

Details

Four ability estimators are available: the maximum likelihood (ML) estimator (Lord, 1980), the Bayes modal (BM) estimator (Birnbaum, 1969), the expected a posteriori (EAP) estimator (Bock and Mislevy, 1982) and the weighted likelihood (WL) estimator (Warm, 1989). The selected estimator is specified by the `method` argument, with values "ML", "BM", "EAP" and "WL" respectively.

For the BM and EAP estimators, three prior distributions are available: the normal distribution, the uniform distribution and Jeffreys' prior distribution (Jeffreys, 1939, 1946). The prior distribution is specified by the argument `priorPar`, with values "norm", "unif" and "Jeffreys", respectively. The `priorPar` argument is ignored if `method="ML"` or `method="WL"`.

The argument `priorPar` determines either the prior mean and standard deviation of the normal prior distribution (if `priorDist="norm"`), or the range for defining the prior uniform distribution (if `priorDist="unif"`). This argument is ignored if `priorDist="Jeffreys"`.

The `eapPar` argument sets the range and the number of quadrature points for numerical integration in the EAP process. By default, it takes the vector value $(-4, 4, 20)$, that is, 20 quadrature points on the range $[-4; 4]$. See `eapEst` for further details.

The `range` argument permits to limit the interval of investigation for the ML, BM and WL ability estimates (in particular, to avoid infinite ability estimates). The default range is $[-4, 4]$.

Value

The estimated ability level.
