# Package 'vamc' 

October 12, 2022
Type Package
Title A Monte Carlo Valuation Framework for Variable Annuities
Version 0.2.1
Description Implementation of a Monte Carlo simulation engine for valuing synthetic portfolios of variable annuities, which reflect realistic features of common annuity contracts in practice. It aims to facilitate the development and dissemination of research related to the efficient valuation of a portfolio of large variable annuities. The main valuation methodology was proposed by Gan (2017) [doi:10.1515/demo-2017-0021](doi:10.1515/demo-2017-0021).

ageOnePolicy Age One Policy

## Description

Age a VA policy specified in inPolicy from currentDate (specified in inPolicy) to targetDate. The againg scenario is given in fundScen. The time step length is specified in dT. Here we input a rather irrelevant parameter df to "hack" for a more flexible user-defined projection function.

## Usage

ageOnePolicy( inPolicy, mortTable, fundScen, scenDates, dT = 1/12, targetDate, df
)

## Arguments

inPolicy A vector containing 45 attributes of a VA policy, usually a row of a VA portfolio dataframe.
mortTable A dataframe with three columns of doubles representing the mortality table.

| fundScen | A numScen-by-numStep-by-numFund array of doubles of return factors (i.e., <br> exp(mu_t dt)) in each period. |
| :--- | :--- |
| scenDates | A vector containing strings in the format of "YYYY-MM-DD" of dates corre- <br> sponding to each period in fundScen. |
| dT | A double of stepsize in years; dT $=1 / 12$ would be monthly. |
| targetDate | A string in the format of "YYYY-MM-DD" of valuation date of the portfolio. |
| df | A vector of doubles of risk-free discount rates of different tenor (not forward <br> rates), should have length being numStep. |

## Value

Outputs a vector containing 45 attributes of a VA policy, where currentDate, gbAmt, GMWBbalance, withdrawal, \& fundValue could be updated as a result of aging. Usually a row of a VA portfolio dataframe.

## Note

Target date MUST be PRIOR to the last date of historical scenario date, Current date MUST be LATER than the first date of historical scenario date.

## Examples

```
exPolicy <- VAPort[1, ]
targetDate <- "2016-01-01"
histFundScen <- genFundScen(fundMap, histIdxScen)
ageOnePolicy(exPolicy, mortTable, histFundScen, histDates, dT = 1 / 12,
targetDate, cForwardCurve)
## Not run:
targetDate <- "2001-01-01"
histFundScen <- genFundScen(fundMap, histIdxScen)
ageOnePolicy(exPolicy, mortTable, histFundScen, histDates, dT = 1 / 12,
targetDate, cForwardCurve)
## End(Not run)
## Not run:
exPolicy <- VAPort[1, ]
exPolicy[1, c("currentDate", "issueDate")] <- c("2001-01-01", "2001-01-01")
histFundScen <- genFundScen(fundMap, histIdxScen)
ageOnePolicy(exPolicy, mortTable, histFundScen, histDates, dT = 1 / 12,
targetDate, cForwardCurve)
## End(Not run)
```

```
agePortfolio Age a Portfolio
```

## Description

Age a portfolio of VA policies specified in each inPolicy of inPortfolio from currentDate (specified in inPolicy) to targetDate. The againg scenario is given in fundScen. The time step length is specified in dT. Here we input a rather irrelevant parameter df to "hack" for a more flexible userdefined projection function.

## Usage

agePortfolio( inPortfolio, mortTable, fundScen, scenDates, dT = 1/12, targetDate, df
)

## Arguments

inPortfolio A dataframe containing numPolicy rows and 45 attributes of each VA policy.
mortTable A dataframe with three columns of doubles representing the mortality table.
fundScen A numScen-by-numStep-by-numFund array of doubles of return factors (i.e., $\left.\exp \left(m u \_t d t\right)\right)$ in each period.
scenDates A vector containing strings in the format of "YYYY-MM-DD" of dates corresponding to each period in fundScen.
dT A double of stepsize in years; $\mathrm{dT}=1 / 12$ would be monthly.
targetDate A string in the format of "YYYY-MM-DD" of valuation date of the portfolio.
df A vector of doubles of risk-free discount rates of different tenor (not forward rates), should have length being numStep.

## Value

Outputs a dataframe containing numPolicy rows and 45 attributes of each VA policy, where currentDate, gbAmt, GMWBbalance, withdrawal, \& fundValue of each policy could be updated as a result of aging.

## Note

Target date MUST be PRIOR to the last date of historical scenario date, Current date MUST be LATER than the first date of historical scenario date.

## Examples

```
    targetDate <- "2016-01-01"
    histFundScen <- genFundScen(fundMap, histIdxScen)
    agePortfolio(VAPort[1:2, ], mortTable, histFundScen, histDates, dT = 1 / 12,
    targetDate, cForwardCurve)
    ## Not run:
    targetDate <- "2001-01-01"
    histFundScen <- genFundScen(fundMap, histIdxScen)
    agePortfolio(VAPort, mortTable, histFundScen, histDates, dT = 1 / 12,
    targetDate, cForwardCurve)
    ## End(Not run)
    ## Not run:
    VAPort[1, c("currentDate", "issueDate")] <- c("2001-01-01", "2001-01-01")
    histFundScen <- genFundScen(fundMap, histIdxScen)
    agePortfolio(VAPort, mortTable, histFundScen, histDates, dT = 1 / 12,
    targetDate, cForwardCurve)
    ## End(Not run)
```

    buildCurve Build Curve
    
## Description

Bootstrap discount factors from a yield curve.

## Usage

```
buildCurve(
    swapRates,
    tenors,
    fixFreq = 6,
    fixDCC = "Thirty360",
    fltFreq = 6,
    fltDCC = "Thirty360",
    calendar = "General",
    bdc = c("Actual", "Preceding", "Following", "Modified_Prec", "Modified_Foll"),
    curveDate,
    numSetDay,
    yieldCurveDCC = "Thirty360",
    holidays = NULL
)
```

## Arguments

| swapRates | A vector of doubles of swap rates. |
| :--- | :--- |
| tenors | A vector of integers of corresponding tenors. |

| fixFreq | An integer of fixed leg frequency of payment in months. Default is 6 , semi-annual payments. |
| :---: | :---: |
| fixDCC | A string of fixed leg day count convention from four options: "Thirty360", "ACT360", "ACT365", or "ACTACT". <br> Default is "Thirty360". |
| fltFreq | An integer of floating leg frequency of payment in months. Default is 6, semi-annual payments. |
| fltDCC | A string of floating leg day count convention from four options: "Thirty360", "АСТ360", "АСТ365", or "АСТАСТ". <br> Default is "Thirty360". |
| calendar | A string of the desired calendar convention from two options: <br> - "NY": New York holiday calendar <br> - "General": all weekdays are business days |
| bdc | A string of business day convention from five options: <br> - "Actual": No rolling on the date applied even if it is a non-business day <br> - "Preceding": 1st business day before holiday <br> - "Following": 1st business day after holiday <br> - "Modified_Prec": Same as "Preceding" unless it belongs to a different month, in which case 1st business day after holiday <br> - "Modified_Foll": Same as "Following" unless it belongs to a different month, in which case 1st business day before holiday |
|  | Default is "Actual". |
| curveDate | A string in the format of "YYYY-MM-DD" of yield curve date. |
| numSetDay | An integer of settlement days from yield curve date. |
| yieldCurveDCC | A string of yield curve day count convention from four options: "Thirty360", "ACT360", "ACT365", or "ACTACT". Default is "Thirty360". |
| holidays | An optional vector dates of user-defined holidays. If provided, within the given holidays range, the calendar provided in the parameter "calendar" will not be applied; |
|  | If the date is not in the given holidays range, it will follow the calendar provided in the "calendar" parameter |

## Value

Outputs a data frame of strings of discount dates and doubles of discount factors.

## Examples

```
rate <- c(0.69, 0.77, 0.88, 1.01, 1.14, 1.38, 1.66, 2.15) * 0.01
tenor <- c(1, 2, 3, 4, 5, 7, 10, 30)
fixFreq <- 6
fixDCC <- "Thirty360"
fltFreq <- 6
fltDCC <- "ACT360"
```

```
calendar <- "NY"
bdc <- "Modified_Foll"
curveDate <- "2016-02-08"
numSetDay <- 2
yieldCurveDCC <- "Thirty360"
holidays <- NULL
buildCurve(rate, tenor, fixFreq, fixDCC, fltFreq, fltDCC, calendar, bdc,
    curveDate, numSetDay, yieldCurveDCC, holidays)
```

    calcMortFactors Calculate Mortality Factors
    
## Description

Calculates the mortality factors $(\mathrm{t}-1) \mathrm{px} \mathrm{q}(\mathrm{x}+\mathrm{t}-1)$ and tpx required to valuate the inPolicy. Extract gender, age (birth date \& current date), valuation date (current date), and maturity date from inPolicy, mortality rates from mortTable.

## Usage

calcMortFactors(inPolicy, mortTable, dT = 1/12)

## Arguments

| inPolicy | A vector containing 45 attributes of a VA policy, usually a row of a VA portfolio <br> dataframe. |
| :--- | :--- |
| mortTable | A dataframe with three columns of doubles representing the mortality table. |
| dT | A double of stepsize in years; $\mathrm{dT}=1 / 12$ would be monthly. |

## Value

Outputs a two-column data frame of doubles of mortFactors $(t-1) p x q(x+t-1)$ and $t p x$.

## Examples

```
exPolicy <- VAPort[1, ]
calcMortFactors(exPolicy, mortTable, dT = 1 / 12)
```

## Description

A dataset containing 2 percent continuously compounded annual interest rate for illustration purposes.

## Usage

cForwardCurve

## Format

A vector with 360 elements:
rate discount rate ...
fundMap Fund Map for 10 Funds

## Description

A dataset containing a default mapping from five indices to ten different funds.

## Usage

fundMap

## Format

A matrix with 10 rows and 5 columns:
index name name for each index
fund number proportion of fund allocated to a particular index ...

## genFundScen <br> Generate Fund Scenerio

## Description

Calculate numScen-by-numStep-by-numFund fund scenarios based on given index scenarios indexScen and fund map fundMap that maps indices to funds.

## Usage

genFundScen(fundMap, indexScen)

## Arguments

$$
\begin{array}{ll}
\text { fundMap } & \text { A numFund-by-numIndex matrix of doubles, mapping indices to funds. } \\
\text { indexScen } & \text { A numScen-by-numStep-by-numIndex array of doubles, index scenarios. }
\end{array}
$$

## Value

Outputs a numScen-by-numStep-by-numFund array of doubles of fund scenarios.

## Examples

```
    genFundScen(fundMap, indexScen)
```

genIndexScen Generate Index Scenerio

## Description

Simulate a 3D array, numScen-by-numStep-by-numIndex, of Black-Scholes return factors for numIndex indices in each of numStep time steps and each of numScen scenarios. Covariances among indices are specified in covMatrix. Stepsize is given is dT and interpolated discount factors are given in vDF. Random seed is optional for reproducibility.

## Usage

genIndexScen( covMatrix, numScen, numStep, indexNames, dT = 1/12, forwardCurve, seed
)

## Arguments

covMatrix A numIndex-by-numIndex matrix of doubles of covariances among numIndex indices.
numScen An integer of number of scenario (sample paths) to be simulated.
numStep An integer of number of periods to be simulated.
indexNames A vector of strings containing index names.
dT A double of stepsize in years; $\mathrm{dT}=1 / 12$ would be monthly.
forwardCurve A vector of doubles of discount rates at each time step.
seed An integer of the deterministic seed for random sampling.

## Value

Outputs a 3D array (numScen-by-numStep-by-numIndex) of index scenarios

## Examples

```
genIndexScen(mCov, 100, 360, indexNames, 1 / 12, cForwardCurve, 1)
```

```
genPortInception Generate Portfolio at Inception
```

## Description

Generate a portfolio of VA contracts at inception based on given attribute ranges and investment fund information.

## Usage

```
genPortInception(
    birthDayRng = c("1950-01-01", "1980-01-01"),
    issueRng = c("2001-08-01", "2014-01-01"),
    matRng = c(15, 30),
    acctValueRng = c(50000, 5e+05),
    femPct = 0.4,
    fundFee = c(30, 50, 60, 80, 10, 38, 45, 55, 47, 46),
    baseFee = 200,
    prodPct = rep(1/19, 19),
    prodType = c("DBRP", "DBRU", "DBSU", "ABRP", "ABRU", "ABSU", "IBRP", "IBRU", "IBSU",
    "MBRP", "MBRU", "MBSU", "WBRP", "WBRU", "WBSU", "DBAB", "DBIB", "DBMB", "DBWB"),
    riderFee =c(25, 35, 35, 50, 60, 60, 60, 70, 70, 50, 60, 60, 65, 75, 75, 75, 85, 75,
            90),
        rollUpRate = rep(5, 19),
        withdrawalRate = rep(5, 19),
        numPolicy = 10
    )
```

## Arguments

| birthDayRng | A vector of two strings in 'YYYY-MM-DD' of birthday range. |
| :--- | :--- |
| issueRng | A vector of two strings in 'YYYY-MM-DD' of issue date range. |
| matRng | A vector of two integers, range of policy maturity. |
| acctValueRng | A vector of two doubles, range of initial account values. |
| femPct | A double, percentage of female policyholders in the portfolio. |
| fundFee | A vector of doubles, fees charged by each fund in bps. |
| baseFee | A double, base fee for all funds in bps. |
| prodPct | A vector of non-negative doubles, proportions of rider types. |
| prodType | A vector of strings, names of different rider types. |
| riderFee | A vector of doubles, rider fees for different riders in bps. |
| rollUpRate | A vector of doubles, roll up rates for different rider types in bps. |
| withdrawalRate | A vector of doubles, withdrawal rates for different rider types in bps. |
| numPolicy | An integer, number of each type of policies to be generated. |

## Value

Outputs a data frame of 45 columns of attributes in an annuity contract.

## Examples

```
genPortInception(c("1980-01-01", "1990-01-01"), c("2001-08-01", "2014-01-01"),
c(15, 30), c(5e4, 5e5), 0.4, c(30, 50, 60, 80, 10, 38, 45, 55, 47, 46),
200, rep(1 / 4, 4), c("WBRP", "WBRU", "WBSU", "DBWB"),
riderFee = c(25, 35, 35, 50), rep(5, 4), rep(5, 4), 100)
## Not run:
genPortInception()
## End(Not run)
```

histDates Historical Scenario Dates

## Description

A dataset containing the dates at which historical returns for different indices were observed.

## Usage

histDates

## Format

A vector with 175 elements:
date each observation date of the historical scenarios ...

## Description

A dataset containing a matrix, number of indices (5) by number of time steps (175), of observed historical returns for each index in each of time step in the past.

## Usage

histIdxScen

## Format

A data frame with dimensions 175 rows and 10 columns:
FIXED historical return for index "FIXED" in one month
INT historical return for index "INT" in one month
MONEY historical return for index "MONEY" in one month
SMALL historical return for index "SMALL" in one month
US historical return for index "US" in one month ...

## Remark

These historical index scenarios were assessed on 2008-09-12

## Source

http://www.math.uconn.edu/~gan/software.html

```
indexNames Index Names
```

## Description

A dataset containing names for each index.

## Usage

indexNames

## Format

A vector with 5 elements:
name name of the index ...

```
indexScen 5 Indices for 10 Scenarios over 360 Months
```

## Description

A dataset containing a 3D array, number of scenarios (10) by number of indices (5) by number of time steps (360), of Black-Scholes return factors for each index in each of time step and each of scenario.

## Usage

indexScen

## Format

A 3D array with dimensions $10 \times 360 \times 5$ :
scenario scenario number
month month since valuation date
index number monthly return for a particular index in one scenario one month ...

> mCov

Covariance Matrix for 5 Indices

## Description

A dataset containing the covariance matrix among the returns of five indices.

## Usage

mCov

## Format

A matrix with 5 rows and 5 columns:
index number number for each index ...
mortTable Mortality Rate for Male and Female from Ages 5 to 115

## Description

A dataset containing the mortality rates for male and female from ages 5 to 115 (table IAM 1996 from the Society of Actuaries).

## Usage

mortTable

## Format

A data frame with 110 rows and 3 columns:
age individual's age
male mortality of a male at a particular age ranging from 5 to 115
female mortality of a female at a particular age ranging from 5 to 115 ...

## Source

https://mort.soa.org
swapRate Swap Rates across 30 Years

## Description

A dataset containing US swap rates for various maturities.

## Usage

swapRate

## Format

A vector with 8 elements:
rate swap rate ...

## Remark

These swap rates were assessed on 2016-02-08

## Source

http://www.federalreserve.gov

```
    valuateOnePolicy Valuate One Policy
```

## Description

Valuate a VA policy specified in inPolicy based on the simulated fund scenarios fundScen. The time step length is specified in dT and the discount rate for each period is specified in df.

## Usage

valuateOnePolicy(inPolicy, mortTable, fundScen, $\mathrm{dT}=1 / 12$, df )

## Arguments

inPolicy A vector containing 45 attributes of a VA policy, usually a row of a VA portfolio dataframe.
mortTable A dataframe with three columns of doubles representing the mortality table.
fundScen A numScen-by-numStep-by-numFund array of doubles of return factors (i.e., $\left.\exp \left(m u \_t d t\right)\right)$ in each period.
dT A double of stepsize in years; $\mathrm{dT}=1 / 12$ would be monthly.
df A vector of doubles of risk-free discount rates of different tenor (not forward rates), should have length being numStep.

## Value

Outputs a list of doubles of policyValue, the average discounted payoff of the VA, and riskCharge, the average discounted risk charges.

## Examples

```
fundScen <- genFundScen(fundMap, indexScen)[1, , ]
exPolicy <- VAPort[1, ]
valuateOnePolicy(exPolicy, mortTable, fundScen, 1 / 12, cForwardCurve)
```

```
valuatePortfolio Valuate a Portfolio
```

## Description

Valuate a portfolio VA policies specified in each curPolicy of inPortfolio based on the simulated fund scenarios fundScen. The time step length is specified in dT and the discount rate for each period is specified in df.

## Usage

valuatePortfolio(inPortfolio, mortTable, fundScen, $d T=1 / 12, d f$ )

## Arguments

inPortfolio A dataframe containing numPolicy rows and 45 attributes of each VA policy.
mortTable A dataframe with three columns of doubles representing the mortality table.
fundScen A numScen-by-numStep-by-numFund array of doubles of return factors (i.e., $\left.\exp \left(m u \_t d t\right)\right)$ in each period.
dT A double of stepsize in years; $\mathrm{dT}=1 / 12$ would be monthly.
df A vector of doubles of risk-free discount rates of different tenor (not forward rates), should have length being numStep.

## Value

Outputs a list of doubles of portVal, the sum of average discounted payoff of the VAs in inPortfolio, portRC, the sum of average discounted risk charges of the VAs in inPortfolio, and vectors of doubles of these average discounted values for each policy.

## Examples

fundScen <- genFundScen(fundMap, indexScen)[1, , ]
valuatePortfolio(VAPort[1:2, ], mortTable, fundScen, 1 / 12, cForwardCurve)

```
vamc
vamc: A package for pricing a pool of variable annuities.
```

## Description

The vamc package provides a Monte Carlo engine for valuating a pool of variable annuities. The key steps are: YieldCurveGeneration, ScenarioGeneration, PolicyGenerationl, and MonteCarloValuation.

## YieldCurveGeneration functions

YieldCurveGeneration generates a forward curve from swap rates. The forward curve is obtained by solving for swap rates that equates values of floating and fixed notes.

## ScenarioGeneration functions

ScenarioGeneration generates a random fund scenario under Black-Scholes. After simulating random index scenarios, a fundMap is used to allocate returns of indices to each fund according to proportion of investment.

## PolicyGenerationl functions

PolicyGenerationl randomly generates a pool of variable annuities for user-input birthday range, issue-date range, maturity range, account value range, female percentage, fund management fee, fund base fee, product types, rider fee of each type, roll-up-rate for roll-up featured guarantees, withdrawal rate for GMWB, and number of policies to be generated for each type.

## MonteCarloValuation functions

MonteCarloValuation discounts cash flow from living and death benefits, as well as risk charges for each policy in the portfolio.

VAPort A Randomly Generated Pool of Variable Annuities

## Description

A dataset containing information of the policy and the policy holder.

## Usage

VAPort

## Format

A data frame with 19 row and 45 columns:
recordID Unique identifier of the policy
survivorShip Positive weighting number
gender Gender of the policyholder
productType Product type
issueDate Issue date
matDate Maturity date
birthDate Birth date of the policyholder
currentDate Current date
baseFee M\&E (Mortality \& Expense) fee
riderFee Rider fee
rollUpRate Roll-up rate
gbAmt Guaranteed benefit
gmwbBalance GMWB balance
wbWithdrawalRate Guaranteed withdrawal rate
withdrawal Withdrawal so far
fundNum1 Fund number of the 1st investment fund
fundNum 2 Fund number of the 2 nd investment fund
fundNum3 Fund number of the 3rd investment fund
fundNum4 Fund number of the 4th investment fund
fundNum5 Fund number of the 5th investment fund
fundNum6 Fund number of the 6th investment fund
fundNum7 Fund number of the 7th investment fund
fundNum8 Fund number of the 8th investment fund
fundNum9 Fund number of the 9th investment fund
fundNum 10 Fund number of the 10th investment fund
fundValue1 Fund value of the 1st investment fund
fundValue 2 Fund value of the 2 nd investment fund
fundValue 3 Fund value of the 3rd investment fund
fundValue4 Fund value of the 4th investment fund
fundValue5 Fund value of the 5th investment fund
fundValue6 Fund value of the 6th investment fund
fundValue7 Fund value of the 7th investment fund
fundValue8 Fund value of the 8th investment fund
fundValue9 Fund value of the 9th investment fund
fundValue10 Fund value of the 10th investment fund
fundFee1 Fund management fee of the 1st investment fund
fundFee 2 Fund management fee of the 2nd investment fund
fundFee3 Fund management fee of the 3rd investment fund
fundFee4 Fund management fee of the 4th investment fund
fundFee5 Fund management fee of the 5th investment fund
fundFee6 Fund management fee of the 6th investment fund
fundFee7 Fund management fee of the 7th investment fund
fundFee8 Fund management fee of the 8th investment fund
fundFee9 Fund management fee of the 9th investment fund
fundFee10 Fund management fee of the 10th investment fund.
